Carbon-supported nickel composite was prepared *in situ* through an impregnation-chemical reduction method and was further investigated as a catalyst for the hydrolytic dehydrogenation of AB (ammonia borane). The supported Ni nanoparticles were uniformly dispersed in the honeycomb-like porous carbon matrix and exhibited high catalytic activity towards the AB hydrolysis reaction, indicating potential application in facile hydrogen generation from borohydride.

Two complexes [CdL(NO₃)₂·H₂O] and [ZnL₂] were synthesized and the structures of the complexes are analyzed via single crystal X-ray diffraction. The antibacterial activities of the ligand and complexes were measured *in vitro*, and the results show that the ligand L and complex **1** possess inhibiting effects to bacteria.

The damaged structure of CNTs has great effect on the compressive mechanical properties of CNTs/HA composites. Among the K (a), C (b) and J methods (c), the CNTs/HA composites prepared by K method have the best compressive mechanical properties, owing to slightest damage to tube wall and length of CNTs.

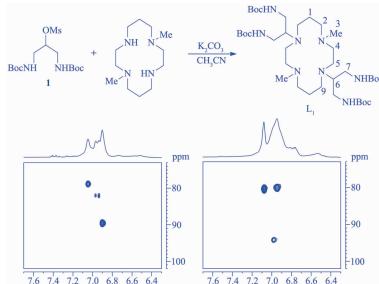

The extraction efficiency of TODGA/[C₂mim][NTf₂] system against Th⁴⁺ decreased first and then increased with the increasing of acidity, TODGA/[C₂mim][NTf₂] system had better extraction efficiency than TODGA/isooctane system especially at low acidity.
